(54) Recording sheets containing amino acids, hydroxy acids, and polycarboxyl compounds.

(57) A recording sheet which comprises a paper substrate and a material selected from the group consisting of monomeric amino acids, monomeric hydroxy acids, monomeric polycarboxyl compounds, and mixtures thereof. Another embodiment of the present invention is directed to a recording sheet which comprises a substrate and a material selected from the group consisting of monomeric amino acids, monomeric hydroxy acids, and mixtures thereof.

EP 0 667 246 A1

The present invention is directed to recording sheets, such as transparency materials, filled plastics, papers, and the like. More specifically, the present invention is directed to recording sheets particularly suitable for use in ink jet printing processes.

South African Patent Application 924,610 discloses a transparent recording sheet suitable for making visual transparencies which comprises a thin transparent film backing bearing on at least one major surface thereof of an ink jet receptive layer comprising from 1% to 10% of at least one acid having a pKa of from 2 to 6, said acid being selected from the group consisting of aryl monocarboxylic acids, aryloxy monocarboxylic acids, alkyl carboxylic acids having alkyl groups containing at least 11 carbon atoms, dicarboxylic acids, tricarboxylic acids, and pyridinium salts, and at least one liquid-absorbent polymer comprising from 90% to 99% aprotic constituents, wherein said sheet shows reduced fading when imaged with an ink containing triarylmethane dye and at least one nucleophile over an identical composition containing no protic organic-solvent-soluble additive.

While known compositions and processes are suitable for their intended purposes, a need remains for improved recording sheets. In addition, there is a need for improved recording sheets suitable for use in ink jet printing processes. Further, a need remains for recording sheets which exhibit rapid drying times when imaged with aqueous inks. Additionally, there is a need for recording sheets which enable precipitation of a dye from a liquid ink onto the sheet surface during printing processes. A need also remains for recording sheets which are particularly suitable for use in printing processes wherein the recorded substrates are imaged with liquid inks and dried by exposure to microwave radiation. Further, there is a need for recording sheets coated with a discontinuous, porous film. There is also a need for recording sheets which, subsequent to being imaged with an aqueous ink, exhibit reduced curling.

It is an object of the present invention to provide recording sheets with the above noted advantages.

These and other objects of the present invention (or specific embodiments thereof) can be achieved by providing a recording sheet which comprises a paper substrate and a material selected from the group consisting of monomeric amino acids, monomeric hydroxy acids, monomeric polycarboxyl compounds, and mixtures thereof. Another embodiment of the present invention is directed to a recording sheet which comprises a substrate and a material selected from the group consisting of monomeric amino acids, monomeric hydroxy acids, and mixtures thereof.

The recording sheets of the present invention comprise a substrate and at least one compound selected from the group consisting of amino acids, hydroxy acids, polycarboxyl compounds, and mixtures thereof. Any suitable substrate can be employed. Examples include transparent materials, such as polyester, including Mylar™, available from E.I. Du Pont de Nemours & Company, and the like, with polyester such as Mylar™ being preferred in view of its availability and relatively low cost. The substrate can also be opaque, including opaque plastics. Filled plastics can also be employed as the substrate, particularly when it is desired to make a "never-tear paper" recording sheet. Paper is also suitable, including plain papers such as Xerox® 4024, diazo papers, or the like.

Further alternative substrates are mentioned in U.S. application S.N. 08/196,679.

The substrate can be of any effective thickness. Typical thicknesses for the substrate are from about 50 to about 500 µm, and preferably from about 100 to about 125 µm, although the thickness can be outside these ranges.

Situated on the substrate of the present invention is an additive material selected from the group consisting of amino acids, hydroxy acids, polycarboxyl compounds, and mixtures thereof.

and the like.

Mixtures of two or more of any of the above compounds can also be employed.

The amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof is present in any effective amount relative to the substrate. Typically, the amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof is present in an amount of from about 1 to about 50 percent by weight of the substrate, preferably from about 5 to about 30 percent by weight of the substrate, although the amount can be outside this range. The amount can also be expressed in terms of the weight of amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof per unit area of substrate. Typically, the amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof is present in an amount of from about 0.8 to about 40 grams per square meter of the substrate surface to which it is applied, and preferably from about 4 to about 24 grams per square meter of the substrate surface to which it is applied, although the amount can be outside these ranges.

When the amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof is applied to the substrate

as a coating, the coatings employed for the recording sheets of the present invention can include an optional binder in addition to the amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof. Examples of suitable binder polymers include (a) hydrophilic polysaccharides and their modifications, (b) vinyl polymers, (c) formaldehyde resins, (d) ionic polymers, (e) latex polymers, (f) maleic anhydride and maleic acid containing polymers, (g) acrylamide containing polymers, and (h) poly(alkylene imine) containing polymers where alkylene has two (ethylene), three (propylene), or four (butylene) carbon atoms, as well as blends or mixtures of any of the above, with starches and latexes being particularly preferred because of their availability and applicability to paper. Numerous examples of such binder polymers are mentioned in U.S. application S.N. 08/196,679, a copy of which was filed with the present application. Any mixtures of the above ingredients in any relative amounts can be employed.

If present, the binder can be present within the coating in any effective amount; typically the binder and the amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof are present in relative amounts of from about 10 percent by weight binder and about 90 percent by weight amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof to about 99 percent by weight binder and about 1 percent by weight amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof, although the relative amounts can be outside of this range.

In addition, the coating of the recording sheets of the present invention can contain optional antistatic agents. Any suitable or desired antistatic agent or agents can be employed, such as quaternary salts and other materials. The antistatic agent can be present in any effective amount; typically, the antistatic agent is present in an amount of from about 1 to about 5 percent by weight of the coating, and preferably in an amount of from about 1 to about 2 percent by weight of the coating, although the amount can be outside these ranges.

Further, the coating of the recording sheets of the present invention can contain one or more optional biocides. Examples of suitable biocides include (A) non-ionic biocides, (B) anionic biocides, (C) cationic biocides, and the like, as well as mixtures thereof. Specific examples of suitable biocides are mentioned in U.S. application S.N. 08/196,679. The biocide can be present in any effective amount; typically, the biocide is present in an amount of from about 10 parts per million to about 3 percent by weight of the coating, although the amount can be outside this range.

Additionally, the coating of the recording sheets of the present invention can contain optional filler components. Fillers can be present in any effective amount, and if present, typically are present in amounts of from about 1 to about 60 percent by weight of the coating composition. Examples of filler components include colloidal silicas, such as Syloid 74, available from Grace Company (preferably present, in one embodiment, in an amount of about 20 weight percent). Brightener fillers can enhance color mixing and assist in improving print-through in recording sheets of the present invention.

The coating containing the amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof is present on the substrate of the recording sheet of the present invention in any effective thickness. Typically, the total thickness of the coating layer (on each surface, when both sides of the substrate are coated) is from about 1 to about 25 μm and preferably from about 5 to about 10 μm , although the thickness can be outside of these ranges.

The amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof, or the mixture of amino acid, hydroxy acid, polycarboxyl compound, or mixture thereof with an optional binder, optional antistatic agent, optional biocide, and/or optional filler can be applied to the substrate by any suitable technique, such as size press treatment, dip coating, reverse roll coating, extrusion coating, or the like. For example, the coating can be applied with a KRK size press (Kumagai Riki Kogyo Co., Ltd., Nerima, Tokyo, Japan) by dip coating and can be applied by solvent extrusion on a Faustel Coater. The KRK size press is a lab size press that simulates a commercial size press. This size press is normally sheet fed, whereas a commercial size press typically employs a continuous web. On the KRK size press, the substrate sheet is taped by one end to the carrier mechanism plate. The speed of the test and the roll pressures are set, and the coating solution is poured into the solution tank. A 4 liter stainless steel beaker is situated underneath for retaining the solution overflow. The coating solution is cycled once through the system (without moving the substrate sheet) to wet the surface of the rolls and then returned to the feed tank, where it is cycled a second time. While the rolls are being "wetted", the sheet is fed through the sizing rolls by pressing the carrier mechanism start button. The coated sheet is then removed from the carrier mechanism plate and is placed on a 12 inch by 40 inch (30.5x102cm) sheet of 750 μm thick Teflon for support and is dried on the Dynamic Former drying drum and held under restraint to prevent shrinkage. The drying temperature is approximately 105°C. This method of coating treats both sides of the substrate simultaneously.

In dip coating, a web of the material to be coated is transported below the surface of the liquid coating composition by a single roll in such a manner that the exposed site is saturated, followed by removal of any excess coating by the squeeze rolls and drying at 100°C in an air dryer. The liquid coating composition gen-

erally comprises the desired coating composition dissolved in a solvent such as water, methanol, or the like. The method of surface treating the substrate using a coater results in a continuous sheet of substrate with the coating material applied first to one side and then to the second side of this substrate. The substrate can also be coated by a slot extrusion process, wherein a flat die is situated with the die lips in close proximity to the web of substrate to be coated, resulting in a continuous film of the coating solution evenly distributed across one surface of the sheet, followed by drying in an air dryer at 100°C.

Recording sheets of the present invention can be employed in ink jet printing processes. Ink jet printing processes are well known, and are described in, for example, US-A-4,601,777, US-A-4,251,824, US-A-4,410,899, US-A-4,412,224, and US-A-4,532,530. In a particularly preferred embodiment, the printing apparatus employs a thermal ink jet process wherein the ink in the nozzles is selectively heated in an imagewise pattern, thereby causing droplets of the ink to be ejected in imagewise pattern. In another preferred embodiment, the substrate is printed with an aqueous ink and thereafter the printed substrate is exposed to microwave radiation, thereby drying the ink on the sheet. Printing processes of this nature are disclosed in, for example, U.S. Patent 5,220,346, the disclosure of which is totally incorporated herein by reference.

The recording sheets of the present invention can also be used in any other printing or imaging processes, such as printing with pen plotters, handwriting with ink pens, offset printing processes, or the like, provided that the ink employed to form the image is compatible with the ink receiving layer of the recording sheet.

Recording sheets of the present invention exhibit reduced curl upon being printed with aqueous inks, particularly in situations wherein the ink image is dried by exposure to microwave radiation. Generally, the term "curl" refers to the distance between the base line of the arc formed by recording sheet when viewed in cross-section across its width (or shorter dimension - for example, 8.5 inches (21.6cm) in an 8.5 × 11 inch (21.6x27.9) sheet, as opposed to length, or longer dimension - for example, 11 inches (27.9cm) in an 8.5 × 11 inch (21.6x27.9cm) sheet) and the midpoint of the arc. To measure curl, a sheet can be held with the thumb and forefinger in the middle of one of the long edges of the sheet (for example, in the middle of one of the 11 inch (27.9cm) edges in an 8.5 × 11 inch (21.6x27.9cm) sheet) and the arc formed by the sheet can be matched against a pre-drawn standard template curve.

Specific embodiments of the invention will now be described in detail. These examples are intended to be illustrative, and the invention is not limited to the materials, conditions, or process parameters set forth in these embodiments. All parts and percentages are by weight unless otherwise indicated.

The optical density measurements recited herein were obtained on a Pacific Spectrograph Color System. The system consists of two major components, an optical sensor and a data terminal. The optical sensor employs a 6 inch (15cm) integrating sphere to provide diffuse illumination and 8 degrees viewing. This sensor can be used to measure both transmission and reflectance samples. When reflectance samples are measured, a specular component may be included. A high resolution, full dispersion, grating monochromator was used to scan the spectrum from 380 to 720 nanometers. The data terminal features a 12 inch (30cm) CRT display, numerical keyboard for selection of operating parameters and the entry of tristimulus values, and an alphanumeric keyboard for entry of product standard information.

EXAMPLE I

Transparency sheets were prepared as follows. Blends of 70 percent by weight hydroxypropyl methyl cellulose (K35LV, obtained from Dow Chemical Co.) and 30 percent by weight of various additive compositions, each obtained from Aldrich Chemical Co., were prepared by mixing 56 grams of hydroxypropyl methyl cellulose and 24 grams of the additive composition in 1,000 milliliters of water in a 2 Liter jar and stirring the contents in an Omni homogenizer for 2 hours. Subsequently, the solution was left overnight for removal of air bubbles. The blends thus prepared were then coated by a dip coating process (both sides coated in one operation) by providing Mylar® base sheets in cut sheet form (8.5 × 11 inches (21.6x27.9cm)) in a thickness of 100 µm. Subsequent to air drying at 25°C for 3 hours followed by oven drying at 100°C for 10 minutes and monitoring the difference in weight prior to and subsequent to coating, the dried coated sheets were each coated with 1 gram, 10 µm in thickness, on each surface (2 grams total coating weight for 2-sided transparency) of the substrate. For comparison purposes, a transparency sheet was also prepared in which the coating consisted of 100 percent by weight hydroxypropyl methyl cellulose and contained no additive composition.

The transparency sheets thus prepared were incorporated into a Hewlett-Packard 500-C color ink jet printer containing inks of the following compositions:

- by weight water.
- Magenta: 20 percent by weight ethylene glycol, 2.5 percent by weight benzyl alcohol, 1.9 percent by weight ammonium chloride, 0.1 percent by weight Dowicil 150 biocide, obtained from Dow Chemical Co., Midland, MI, 0.05 percent by weight polyethylene oxide (molecular weight 18,500), obtained from Union Carbide Co.), 2.5 percent by weight Triton Direct Red 227, obtained from Tricon, 72.95 percent by weight water.
- Yellow: 20 percent by weight ethylene glycol, 2.5 percent by weight benzyl alcohol, 1.9 percent by weight ammonium chloride, 0.1 percent by weight Dowicil 150 biocide, obtained from Dow Chemical Co., Midland, MI, 0.05 percent by weight polyethylene oxide (molecular weight 18,500), obtained from Union Carbide Co.), 3 percent by weight Hoechst Duasyn Brilliant Yellow SF-GL VP220, obtained from Hoechst, 72.45 percent by weight water.

Images were generated by printing block patterns for magenta, cyan, yellow, and black. The images thus formed were dried by exposure to microwave radiation with a Citizen Model No. JM55581, obtained from Consumers, Mississauga, Ontario, Canada, set at 700 Watts output power at 2450 MHz frequency. The black images were "process black" (i.e., formed by superimposition of cyan, magenta, and yellow images). The drying times and optical densities for the resulting images were as follows:

	Additive	Drying Time (seconds)				Optical Density			
		black	cyan	magenta	yellow	black	cyan	magenta	yellow
20	none	30	20	30	20	2.50	2.07	1.45	0.99

30	L-arginine hydrochloride	10	30	30	20	1.80	2.10	1.65	0.95

As the results indicate, the drying times for the process black images in all cases was faster in the presence of the additives than in their absence. In addition, all of the images exhibited acceptable optical densities.

Blends of 90 percent by weight hydroxypropyl methyl cellulose (K35LV, obtained from Dow Chemical Co.) and 10 percent by weight of various additive compositions, each obtained from Aldrich Chemical Co., were prepared by mixing 72 grams of hydroxypropyl methyl cellulose and 8 grams of the additive composition in 1,000 milliliters of water in a 2 Liter jar and stirring the contents in an Omni homogenizer for 2 hours. Subsequently, the solution was left overnight for removal of air bubbles. The blends thus prepared were then coated by a dip coating process (both sides coated in one operation) by providing Mylar® base sheets in cut sheet form (8.5 x 11 inches (21.6x27.9cm)) in a thickness of 100 µm. Subsequent to air drying at 25°C for 3 hours followed by oven drying at 100°C for 10 minutes and monitoring the difference in weight prior to and subsequent to coating, the dried coated sheets were each coated with 1 gram, 10 µm in thickness, on each surface (2 grams total coating weight for 2-sided transparency) of the substrate. For comparison purposes, a transparency sheet was also prepared in which the coating consisted of 100 percent by weight hydroxypropyl methyl cellulose and contained no additive composition.

The transparency sheets thus prepared were incorporated into a Hewlett-Packard 500-C color ink jet printer containing inks of the following compositions:

Cyan: Same as Example I.

Images were generated by printing block patterns for magenta, cyan, yellow, and black. The images thus formed were allowed to dry at 25°C. The black images were "process black" (i.e., formed by superimposition of cyan, magenta, and yellow images). The drying times and optical densities for the resulting images were as follows:

As the results indicate, the drying times of the transparencies containing the additives was generally faster than the drying times of the transparencies containing no additives, while optical densities of images formed on the transparencies containing the additives remained acceptable.

EXAMPLE III

Paper recording sheets were prepared as follows. Coating compositions containing various additive compositions, each obtained from Aldrich Chemical Co., were prepared by dissolving 50 grams of the additive in 500 milliliters of water in a beaker and stirring for 1 hour at 25°C. The additive solutions thus prepared were then coated onto paper by a dip coating process (both sides coated in one operation) by providing paper base sheets in cut sheet form (8.5 × 11 inches (21.6x27.9cm)) in a thickness of 100 mm. Subsequent to air drying at 100°C for 10 minutes and monitoring the difference in weight prior to and subsequent to coating, the sheets were each coated on each side with 500 milligrams, in a thickness of 5 µm (total coating weight 1 gram for two-sided sheets), of the additive composition. For comparison purposes, an uncoated paper sheet treated with a composition containing only water by the same procedure was also imaged.

The paper sheets thus prepared were incorporated into a Hewlett-Packard 500-C color ink jet printer containing inks of the following composition:

45 Cyan: Same as Example I.

Magenta: Same as Example I.

Yellow: Same as Example 1.

Images were generated with 100 percent ink coverage. After the image was printed, the paper sheets were each weighed precisely in a precision balance at time zero and periodically after that. The difference in weight was recorded as a function of time, 100 minutes being considered as the maximum time required for most of the volatile ink components to evaporate. (Volatiles were considered to be ink components such as water and glycols that can evaporate, as compared to components such as dyes, salts, and/or other non-volatile components. Knowing the weight of ink deposited at time zero, the amount of volatiles in the image can be calculated.) After 1000 minutes, the curl values of the paper were measured and are listed in the Table below. The black images were "process black" (i.e., formed by superimposition of cyan, magenta, and yellow images).

Additive	Percent weight-loss of volatiles at various times (minutes)						1,000 minutes	
	5	10	15	30	60	120	wt. loss %	curl in mm
none	32	43	45	48	50	53	65	125
D,L-2-amino butyric acid	39	51	57	60	64	67	72	30
L-arginine hydrochloride	37	50	54	58	63	66	81	20
D,L-threonine	31	48	55	59	61	65	80	20
N-acetyl-D,L-methionine	38	50	55	59	64	68	90	10
β alanine	27	40	45	47	50	54	83	20
L-tartaric acid	33	49	55	60	64	68	86	15
2-hydroxycinnamic acid	31	47	51	56	58	64	87	15
3-hydroxy benzoic acid	37	52	57	61	63	67	94	5
3,4-dihydroxy cinnamic acid	35	48	52	55	58	64	86	15

As the results indicate, the papers containing the additives exhibited higher weight loss values at time 1,000 minutes compared to the paper which had been treated with water alone. In addition, the papers coated with the salts exhibited lower curl values compared to the curl value for the paper treated with water alone.

EXAMPLE IV

Paper recording sheets were prepared as follows. Coating compositions containing various salt compositions, each obtained from Aldrich Chemical Co., were prepared by dissolving 50 grams of the salt in 500 milliliters of water in a beaker and stirring for 1 hour at 25°C. The salt solutions thus prepared were then coated onto paper by a dip coating process (both sides coated in one operation) by providing paper base sheets in cut sheet form (8.5 x 11 inches (21.6x27.9cm)) in a thickness of 100 μ m. Subsequent to air drying at 100°C for 10 minutes and monitoring the difference in weight prior to and subsequent to coating, the sheets were each coated on each side with 500 milligrams, in a thickness of 5 μ m (total coating weight 1 gram for two-sided sheets), of the salt composition. For comparison purposes, an uncoated paper sheet treated with a composition containing only water by the same procedure was also imaged.

The paper sheets thus prepared were incorporated into a Hewlett-Packard 500-C color ink jet printer containing inks of the following composition:

Cyan: Same as Example I.

Magenta: Same as Example I.

Yellow: Same as Example I.

The black images were "process black" (i.e., formed by superimposition of cyan, magenta, and yellow images). The optical densities for the resulting images were as follows:

Additive	Optical Density			
	black	cyan	magenta	yellow
none	1.08	1.18	1.03	0.80
D,L-2-amino butyric acid	1.26	1.28	1.13	0.78
L-arginine hydrochloride	1.26	1.20	1.15	0.79
D,L-threonine	1.24	1.30	1.08	0.79
N-acetyl-D,L-methionine	1.04	1.05	0.86	0.68
β -alanine	1.20	1.10	1.15	0.80
L-tartaric acid	1.02	1.00	0.84	0.70
2-hydroxycinnamic acid	1.03	1.16	0.70	0.65
3-hydroxy benzoic acid	1.03	1.15	0.71	0.66
3,4-dihydroxy cinnamic acid	1.01	1.11	0.69	0.68

As the results indicate, the papers coated with the additive compositions exhibited acceptable optical densities for all colors.
